Viikinmäki wastewater treatment plant

## INTRODUCTION

### Fouling and contamination of sensors

- Unwanted deposition or contamination from the fluid contact with sensor element that causes signal noise, drift or delays leading to error in measurement
- Classification on mechanism: crystallization, solidification, particle deposition, microbial growth etc. on surface or contamination of electrolyte in ISE electrodes.
- Classification on type of sensor: optical window, metal electrode, membrane fouling or contamination in ISE electrodes

## MITIGATION OF FOULING

Maintenance and cleaning interval, is this acceptable?

- Discrete or continuous measurement
- Manual or automatic cleaning and calibration
- Sensor installation position

Mitigation and cleaning techniques

- Mechanical: brushes, water or air jets
- Chemical: cleaning solutions
- Physical energy: magnetic, radiation, ultra sound
- Material and coating selection

Compensation of signal drift due to fouling and contamination

- Calibration
- Compensation

## TEST CASE IN TASKILA

- Surface material and ultra sound tests at Taskila waste water plant in Oulu
  - Reject water from sludge centrifuges
  - 10 coatings: 9 for metals, 1 optical for sapphire glass
  - Test with and without ultrasound
  - Measurement of fouling after a test period c.a. 2,5h: visual, microscopy, and absorbance measurement for fouling detection
- Chemical analysis from deposited material: SEM-EDS (microanalysis for elements), IR-DRIFT (chemical identification)

# TASKILA VISUAL OBSERVATIONS

- All material fouled
- More fouling with ultra sound (A)
- YO safir fouled more than ref
- YO metal fouled more than ref
- ATV fouled equally to ref
- AR226 and 229 fouled the least and cannot make difference
- All CVD coatings fouled markedly
- particle or growth crystals observed

- Deposited material consist of pale transparent deposit containing dark particles

# CHEMICAL ANALYSIS OF DEPOSITED MATERIAL

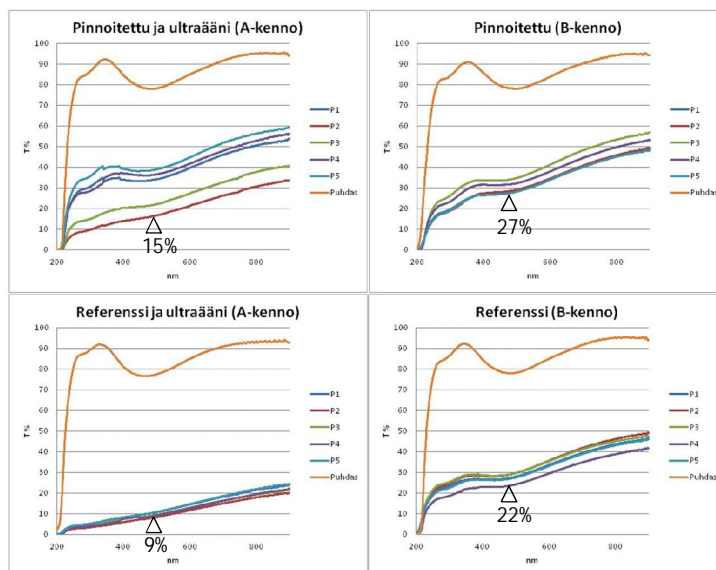

Element	Weight %	Atomic%
O K	8.82	71.76
Al K	0.41	2.00
P K	0.34	1.44
S K	0.12	0.48
Ca K	0.27	0.87
Fe K	10.07	23.45
Totals	20.03	

- **Particles**, X-ray microanalysis → Iron oxides
- **Transparent deposit**, IR-FTIR → waxes and fatty acids

# TRANSMITTANCE

- With ultrasound transmittance dropped more than in ref
- With optical coating transmittance dropped less both with ref and ultrasound

## TASKILA OUTCOME

- Optical windows and metal pieces were tested in reject water of sludge centrifuges
- Fouling was mainly due to fat/wax and oxidized iron particles depositing on sample surfaces
- Aim was to make difference between
  - (1) coatings on fouling susceptibility
  - (2) effectiveness of ultrasound
- In the tests, all surface fouled in 2,5 h
- Deposited material was found to be mostly fatty acids/wax with iron oxide particles
- Ultrasound did not mitigate fouling, probably induced fat droplet coalescence leading to heavier fouling
- Fouling was mitigated by some coating, marked benefit was found with AR 226 and 229 coatings (fluoropolymer coatings)

## TEST CASE IN PEURANIEMI

Optical measurements at Peuraniemi waste water plant in Kajaani

- Waste water after biological filtration, treated plant effluent
- 3 optical cells with quartz windows:
  - (1) air jet (top position),
  - (2) spectrum measurement as reference (middle),
  - (3) continuous UV-light (bottom)
- Fouling detection from spectrum through optical cell trough tap water
- Chemical analysis from deposited material:
  - SEM-EDS (microanalysis for elements),
  - IR-DRIFT (chemical identification)

OULUN YLIOPISTO

## TEST 1 PEURANIEMI PLANT IN KAJAANI

- Top (air-jet) and bottom position (UV light) have small drop in transmittance
- Reference has marked drop especially after 3 weeks

OULUN YLIOPISTO

## TEST 2 PEURANIEMI PLANT IN KAJAANI

- During test period 2 fouling was weak and difference between UV, air-jet and reference could not be made
- Test period 2 was during spring having flood waters: high flow and low P

## PEURANIEMI OUTCOME

- Aim was to find optical window fouling in plant effluent conditions
- Mitigation of fouling was tested using (1) UV light and (2) air jet
- Test periods (2) were during the spring 2015
- In the first test period UV light and air jet was found to mitigate fouling
- In the second test fouling was slow and no clear differences
- Further testing of UV light could be beneficial because in normal operation of waste water plant it was found to mitigate fouling effectively

# CONCLUSIONS

- Ultrasound seem not to be option in fouling mitigation
  - Not effective in waste water application
  - Expensive structure if integrated to a sensor
- Coatings and especially UV light are promising techniques to mitigate fouling in optical measurements
  - UV led gives low-cost source of radiation to be used in connection with optical measurements
  - Optical coatings are demanding to find, most existing ones are anti-reflection coatings and are not optimized for non-fouling
  - Photo catalytic coatings (non-fouling) for windows are known but was not unfortunately tested yet in this work
- In further studies, combination of photo catalytic coating and UV-light would be beneficial to be studied
